PROGRAM REWRITABLE CAMERA

216761

u FIELD OF THE INVENTION AND RELATED ART STATEMENT

P The present invention relates to a program rewritable camera, and more particularly, to a fully
5 automatic camera system which is controlled by data stored in a memory within the camera body.

Recently, the electronization of cameras has taken rapid strides and there have been made a great number of proposals for various functions of cameras
10 which would be difficult to carry out with conventional mechanical cameras. Taking an exposure operation as an example, as a multi-spot photometry, automatic rear light compensation,

✓
multi-program automatic exposure and the like
15 can not be accomplished without an electronic circuit, especially a microcomputer. In the extreme case, it is possible to construct a camera which has a quite different function only by changing a software within a microcomputer even when the camera has the same
20 mechanical structure and electronic circuit arrangement. Therefore, in the current market, there are a great number of cameras of the type in which functions according to photographer's needs are added to fundamental functions for taking pictures.

3
25 Furthermore, there are a number of cameras whose functions are expandable by attaching operating

members as camera accessories to a camera body.

However, the needs in the camera market are so various that it is impossible to satisfy all users with functions provided by camera makers. Consequently, camera users must disadvantageously procure several kinds of cameras which have their desired functions respectively. And yet, it is extremely inconvenient to provide all the manifold needs of users in a single camera body because of shortage of memory capacity in a software and complication in operations and provision of switches and the like.

15
OBJECT AND SUMMARY OF THE INVENTION

It is an object of the present invention to provide a program rewritable camera in which photographer's desired functions can be optionally selected and its operation is extremely simple.

a
3
20 A program rewritable camera according to the present invention, as shown in Fig. 1, comprises a camera element 2 for effecting camera operation, control means 3 for controlling the camera element 2 in response to coded control commands, first memory means 4 for storing the control commands and input means 5 for enabling to rewrite ^{the} part or all of ^{the} stored data in the first memory means 4 by a peripheral device 6 provided on the outside of a camera 1, within the camera 1. It

is possible to store the desired functions in the first memory means 4 from the peripheral device through the input means 5 by connecting the peripheral device 6 to the camera 1.

5 According to the present invention, it is possible to select and store only required ones out of a plurality of functions, yielding the following remarkable effects.

P
10 (1) A function can be optionally set in accordance with purposes of photographing.

a
(2) A ^{camera} ~~camera~~ having ^{the} desired functions can be realized with a single camera.

a
(3) Complication of operation due to unnecessary ^{functions} ~~functions~~ can be eliminated.

15 (4) The reliability is improved because of a reduced number of operating members and a cost is reduced.

a
DETAILED DESCRIPTION OF PREFERRED EMBODIMENTS

Embodiments of ^a program rewritable camera according to the present invention, which will be described hereinafter, comprise a first memory in which a software for effecting fundamental functions of camera operation has been stored as the first memory 4 within

a
the program rewritable camera 1 shown in Fig. 1 and a
second memory into which a software for effecting
photographer desired functions is externally inputted
and stored, thereby controlling camera operations on the
5 basis of the ^{software}~~softwares~~ stored in the first and second
memories with the result of eliminating the
^{complication}~~complication~~ in operating members of a conventional
multi-function camera.
a

A great number of examples of application of
10 the present invention are conceivable. In embodiments
which will be detailed hereinafter, description will be
given with respect to only AF operations and photometric
operations, for the simplification of description.

Fig. 2 is a block diagram of a control system
15 for a fully automatic single-lens reflex camera to which
the present invention is applied, which will be
described in ^{Figs.}~~Fig.~~ 3 to 15.
a

A photometry/exposure control circuit 11,
winding motor control circuit 16, LCD driver 18, DX
20 circuit 20, lens data circuit 21, AF interface circuit
22, AF motor control circuit 24, first memory circuit
26, second memory circuit 27 and switch group 28
including various switches are connected to a main CPU
10. The photometry/exposure control circuit 11 has ^{the}
25 functions of making the A/D conversion of outputs from a
first photometric element 12 which effects photometry of

the center of an image plane and a second photometric
element 13 which effects photometry of the periphery of
an image plane and of transferring the converted outputs
to the main CPU 10, of controlling a motor 14 for
5 controlling a diaphragm aperture (hereinafter referred
to as an AV motor), and of controlling a magnet ¹⁵~~5~~ for
controlling a shutter (hereinafter ^{referred}~~referred~~ to as a
shutter magnet). The winding motor control circuit 16
controls a winding motor 17 in response to a control
10 signal from the main CPU 10. The LCD driver 18 is a
driver for displaying a shutter speed, diaphragm
information and the like on an LCD 19 of a dot matrix ^{type}~~type~~.
The DX circuit 20 reads a DX code from a film cartridge
and ^{transfers}~~transfer~~ it to the main CPU 10. The lens data
15 circuit 21 reads information peculiar to an
interchangeable lens stored thereon (a fully open F
number, minimum F number, focal length, AF coefficients
or the like) and ^{transfers}~~transfer~~ it to the main CPU 10. An AF
interface circuit 22 effects the A/D conversion of an
20 output from an AF sensor 23 and transfers it to the main
CPU 10. An AF motor control circuit 24 controls an AF
motor 25 ^{on}~~on~~ the basis of a control signal from the main
CPU 10. A first memory circuit 26 stores a software ^{program}~~program~~ for
effecting fundamental operations of a camera operation
25 sequence. A second memory circuit 27 reads a software ^{program}~~program~~
for effecting functions which are desired by a

photographer from an outer peripheral device and stores it.

An embodiment of the present invention will be described hereinafter with reference to Figs. 3 and 4.

5 In Fig. 3, a camera body 30 is provided with a ^{power}~~power~~ switch button 31, release button 32 of the two step structure, UP switch 33, DOWN switch 34 and liquid crystal display board 35. On the other hand, a peripheral device 36 is removably connected to a mount
10 30a of the camera body 30 by a connect cable 39. When a software ^{program}₁ is selectively set from a memory device 37 in which a plurality of photographer's desired softwares have been stored (hereinafter referred to ^{as}₁ a ROM pack), the software within the ROM pack 37 is transferred to
15 the second memory circuit 27 (see Fig. 2) in the camera body by operation of an OUT button 38.

Fig. 4 is an electric circuit diagram of essential parts of the camera system mentioned above. When, in the camera body 30, a two-state switch 40 which
20 is opened and closed in response to the power switch button 31, (hereinafter referred to as a power switch), is closed, a power voltage Vcc is applied to the main CPU 10, first memory circuit 26 (hereinafter referred to as a ROM) and second memory circuit 27 (hereinafter
25 referred to as an ^{E²PROM}~~E²PROM~~) and a power-on reset is set to the main CPU 10 by a combination of a resistor 42 and a

a
a
capacitor 43. The ^{E²PROM}~~E²PROM~~ 27 refers to a non-volatile reading and writing memory. The main CPU 10 controls an object 48 to be controlled on the basis of two memory circuits of ROM 26 and ^{E²PROM}~~E²PROM~~ 27.

5 Push switches 46 and 47 are closed in response to the release button. The push switch 46 is closed by the first step of the release button and the push switch 47 is closed by the second step thereof. Push switches 44 and 45 are closed respectively in response to the UP
10 button 33 and DOWN button 34 and their functions are switched by a software ^{Program}~~stored~~ in the ^{E²}~~E²~~ PROM 27.

a
In the peripheral device 36 circuit, when a push switch 51 which is connected to a pull-up resistor 50 is closed in response to the OUT button 38 after the
15 power switch 40 has been closed, a one-shot pulse circuit 49 delivers an interruption signal WINT to the main CPU 10. When a ROM 52 within the ROM pack 37 is mounted on the peripheral device 36, an address bus and a data bus are shared with the main CPU 10 in the camera
20 body 30.

Camera operations of the foregoing embodiment will be described with reference to flow charts shown in Fig. 5. When a voltage Vcc is applied to the main CPU 10, the power-on reset is set to initiate a routine
25 <Power-on reset>. Then, I/O initialization is effected
21 22 and subsequently all interruption operations are

inhibited and information peculiar to a lens is read
from the lens data circuit 21 by a routine <Lens data>.

21 22 Subsequently, a routine <Photometry> is 21 22
called, which is a software stored in the ~~E2PROM~~ ^{E2PROM} 27. In
5 other words, it is a software ^{program} ~~transferred~~ ^{transferred} from the ROM
pack 37 selected by a photographer (Details will be
21 22 described later). In the routine <Photometry>, while
photometric modes vary with respective ROM packs,
display of a shutter speed and diaphragm aperture based
10 on photometric values are made in common.

Subsequently, a photometry timer which
controls a period of photometry operation is set to
enable interruption of the timer and await the half-
depression of the release button 32, that is, the close
15 of the push switch 46. When the release button 32 is
21 22 half-depressed, the flow jumps to a routine <AF> which
has been stored within the ~~E2PROM~~ ^{E2PROM} 27 and which is a
software ^{program} ~~originally transferred~~ from the ROM52 in the
ROM pack 37.

20 Now, a routine of the main CPU 10 conducting
interruption will be described.

The routine of the main CPU conducting
interruption includes a ~~timer~~ ^{TIMER} interruption, WRITE
(write) interruption, REL(release) interruption and
25 RELOFF(release off) interruption. The ~~timer~~ ^{TIMER}
interruption is to enable a photometry display operation

21 22 to be periodically conducted and a routine <Photometry>
is conducted each time of the interruption. Upon

21 22 completion of the routine <Photometry>, the flow returns
to a point where the interruption occurred. The WRITE
5 interruption occurs by an interruption signal WINT which
is delivered from the one-shot pulse generator 49 in the
peripheral device 36. This is a routine in which
contents of the ROM 52 in the ROM pack 37 ^{are} ~~is~~ transferred
to the E2PROM.

a P 10 When the WRITE interruption occurs, all interruptions
are first inhibited and then a first address (read start
address) of the ROM 52 is stored in an IX register and a
first address (write start address) of the ^{E2PROM} ~~E2PROM~~ 27 is
stored in an IY register. Contents of the address
stored in the IX register ^{are} ~~is~~ read ^{into} ~~in~~ an accumulator Acc.

a a a 15 OVS After the R/W terminal is turned to "L" and the ^{E2PROM} ~~E2PROM~~
27 is ^{placed in the} ~~made a~~ Write mode, ^{the} contents of the accumulator ^{are} ~~is~~
written in the address stored in the IY register.

OVS

Then, the R/W terminal is returned to "H".

20 Subsequently, judging whether the stored address is a
final one, if not, adding 1 to the IX and IY registers,
similar operations are repeated. If the final address,
21 the flow returns to the start of the routine <Power-on
22 reset>.

25

The REL interruption occurs when the push
switch 47 is closed by the deep depression of the

release button 32 to its second step.

21, 22³ After all interruptions are inhibited, routines
<Photometry>, <Release> and <Winding> are continuously
conducted.

5 The RELOFF ^{interruption} ~~interruption~~ occurs when the half-
depression of the release button 32 is released during
an AF operation, that is, the push switch 46 is opened
21 22 and returns to the routine <Power-on reset> by
interrupting the AF operation which has been conducted
10 so far.

In the above embodiment, software operations
which are inputted from the outside of a camera are
limited to an AF operation and a photometry operation,
and the AF operation is defined by two of an "AF single
15 operation" and an "AF continuous operation" and the
photometry operation is defined by three of an "average
photometry program AE", "variable center-weighted
photometry program AE" and "average photometry aperture"
priority AE". As a result, the ROM pack 37 is provided
20 with six kinds of combinations of the AF and photometry
operations. In other words, some of all addresses in
the ROM 52 may be allotted separately to the AF and
photometry operations.

25 Each of the subroutines of the AF and
photometry operations will be described with reference
to Figs. 6 to 10.

21

21 22₅

P

21 22

a 21 22 at infinity side, the flow returns. After ^{lens} returned, the flow again returns to the routine <Range detection>.

If the object is not in a low contrast, whether the present lens position is focused is judged.

5 21 22 When focused, an in-focus display is made and a release operation is awaited. If not focused, a routine <Pulse calculation> in which a range difference is converted to a rotating amount of an AF motor is conducted.

Inhibiting the timer interruption, the focusing lens is

10 21 22 moved to the presumed in-focus position in a routine <Lens drive> and the flow returns again to the routine <Range detection>.

L L P This operation is repeated until an in-focus condition is obtained.

21 15 Fig. 7 is a flow chart of a routine <AF continuous> when an AF continuous mode is selected. The 22 routine is substantially the same as the routine <AF single>. In the AF continuous mode, even once focused, only interruption of a release operation is enabled and 20 the next AF operation is immediately initiated.

Consequently, when the object is continuously tracked and the release button 32 is deeply depressed to its second step when focused, the release operation is performed.

25 In addition, in the AF continuous mode, the lens scan operation when the object is in a low contrast

is not conducted, the release interruption is inhibited, an in-focus display is turned off and the range detection is immediately resumed.

The case where an "average photometry program

5 AE" is selected as a photometry routine will be

21 22 described with reference to a routine <Photometry 1>
L L shown in Fig. 8. When the routine <Photometry 1> is called, an ISO sensitivity of a film is first taken in the main CPU 10 from the DX circuit 20 as an SV value.

10 Next, brightness values BV1 and BV2 of an object being photographed in respective first and second photometry circuits 12 and 13 are taken in from the photometry/exposure control circuit 11 and an average value BV is calculated. Subsequently, in a routine
21 22 25 <AV/TV calculation>, a programmed optimum aperture and a shutter speed are calculated based on the SV value, BV value, fully open F No. of a lens (AVo), minimum F No. (AVm), maximum shutter time (TVm), minimum shutter time (TVo) and the like.

20 Thereafter, judging whether the photometry operation is at a first time, if so, 0 is stored in a register N and the flow proceeds to a routine <Display>.
21 22 B

If not, then follows check of conditions of the push switches 44 and 45 which are respectively in response to
25 the UP button 33 and DOWN button 34. When the push switch 44 is on, the UP button 33 is on, so that 1 is

added to a register N. On the other hand, when the push switch 45 is on, the DOWN button 34 is on, so that 1 is subtracted from the register N. B

Subsequently, an aperture (AV value) is
5 corrected by a value in the register N and a shutter speed (TV value) is corrected correspondingly. However, a scope of the correction is not in excess of the foregoing minimum FNo. (AVm), fully open F No. (AVo), maximum shutter time (TVm) and minimum shutter time
10 (TVo). In other words, this is to shift programmed AV and TV values within a scope of proper exposure by depressing the UP button 33 or the DOWN button 34 by a photographer.

Thus, at this time, the UP and DOWN buttons
15 33, 34 serve as a program shift button.

21 22 Subsequently, in the routine <Display>, the present AF and photometry modes are displayed on the LCD 19 with a dot matrix ^{type display} through the LCD driver 18. In addition, functions of the UP and DOWN buttons 33, 34
20 are also displayed on the LCD 19. Consequently, a structure of the display varies with ^{the} ~~a~~ software stored in the ^{E²PROM} ~~E²PROM~~ 27, that is, the one externally inputted.

a
a
The case where a "variable center-weighted photometry program AE" is selected as a photometry
25 routine will be described with reference to a routine <Photometry2> shown in Fig. 9. In this case, the UP and

a
DOWN buttons 33, 34 serve as switching buttons for
changing a ratio in the center-weighted photometry as
compared with the ~~forgoing~~^{judging} routine <Photometry 1>.

The flow reads in SV, BV1, and BV2 values in a
5 manner similar to the routine <Photometry 1> and when
the operation is at a first time, 5 is stored in a
register M. If not a first time, judging whether the UP
button 33 is on, if so, 1 is added to the register M.
If not, then follows check of a condition of the DOWN
10 button 34. If the DOWN button 34 is on, 1 is subtracted
from the register M. The numerical value to be stored
in the register M are not in excess of 1 to 10.

When the register M is set, the BV value is
calculated. Specifically, the variable center-weighted
15 photometry is realized by obtaining the BV value by
giving weight stored in the register M to a brightness
BV1 in the center of a picture plane and a brightness
BV2 in the periphery thereof. Then follows calculation
of a diaphragm aperture and shutter speed in a routine
21 32 <AV/TV calculation>. These values are displayed on the
LCD 19 together with display of AF and photometry modes
and display of functions of the UP and DOWN buttons 33,
34.

The case where an "average photometry aperture"
25 priority AE" is selected as a photometry routine will be
described with reference to a routine <Photometry 3>

22 shown in Fig. 10. Operations to calculation of an
average value BV are similar to the routine <Photometry
1>. 21

5 After an EV value is calculated, if the
operation is at a first time, a diaphragm aperture and
shutter speed are properly set in an ordinary routine
21 22 <AV/TV calculation>. When on and after the second time,
an AD value is shiftable from the minimum F No. (AVm) to
the fully open FNo. (AVo) in accordance with conditions
10 of the UP and DOWN buttons 33, 34. Consequently, the UP
and DOWN buttons 33, 34 in this case serve as a shift
button of an AV value. When an AV value is set, a TV
value is determined by the EV value which has been
previously obtained.

15 When the AV and TV values are determined, AF
and photometry modes are displayed together with
functions of the UP and DOWN buttons 33, 34 in a routine
21 22 <Display>.

A second embodiment of the present invention
20 will be described with reference to Figs. 11 and 12. In
the second embodiment, a plurality of additional
functions are stored in a ROM of a large capacity in a
peripheral device so as to transfer functions which a
photographer desires to a memory in the camera body. In
25 Fig. 11, a peripheral device 53 is adapted to be
connected to a mount 30a of the camera body 30 by a

a
a
connect cable 61. In addition, on the upper surface of the device 53 are arranged AF single button 54 and AF continuous button 55 for selecting AF modes, ^{Photometry}~~photometry~~ 1 button 56, ^{Photometry}~~photometry~~ 2 button 57, ^{Photometry}~~photometry~~ 3 button 58, OUT button 59 and RESET button 60 for selecting photometry modes.

Fig. 12 shows an electric circuit of the peripheral device 53. In Fig. 12, since an electric circuit of the camera body 30 is the same as that shown in Fig. 4, it is omitted. When a sub-CPU 62 and a ROM 63 are connected to the camera body, they share an address bus and data bus with the main CPU 10 in the camera body 30. When the peripheral device 53 is connected to the camera body 30 by the connect cable 61, a power voltage Vcc is supplied to the sub-CPU 62 and ROM 63 from the camera body 30 and a power-on reset is set to the sub-CPU 62 by a combination of a resistor 65 and a capacitor 72.

a
Push switches 66, 67, 68, 69, 70 and 71 are closed in response to the AF single button 54, AF continuous button 55, ^{Photometry}~~photometry~~ 1 button 56, ^{Photometry}~~photometry~~ 2 button 57, photometry 3 button 58 and OUT button 59.

A push switch 64 is closed in response to the RESET button 60 to set the sub-CPU 62 to a reset. In the second embodiment, since the sub-CPU 62 extracts subroutines for conducting functions selected by a

a
photographer from the ROM 63 in the peripheral device 53
and transfers them to the ^{E²}~~E²~~ PROM 27 in the camera body,
operations of the main CPU 10 only differs from those of
the first embodiment in a routine <WRITE interruption>,
5 as shown in Fig. 13. 21 22

In operation, the routine <WRITE interruption>
shown in Fig. 13 will be described. 21 The interruption 22
occurs when the sub-CPU 62 renders an interruption
signal WINT "L" to the main CPU 10. Upon occurrence of
10 the interruption, after all interruptions are inhibited,
OVS an R/W signal is turned to "L" to render the ~~E²PROM~~ ^{E²PROM in the} a
WRITE mode, thereafter awaiting until the interruption
signal WINT becomes "H". Detecting that the signal WINT
OVS becomes "H", the R/W signal is returned to "H" to return
21 22 25 to a routine <Power-on reset>.

Fig. 14 shows a flow chart of operations of
the sub-CPU 62 in the peripheral device 53. When set to
the power-on reset, the sub-CPU 62 conducts the routine
21 22 <Power-on reset>. First, in order to set an initial
20 mode, an address (ADR 1 address) in which the routine
21 22 <Photometry 1> has been stored is stored in a register
IX and an address (ADR 4 address) in which the routine
21 22 <AF single> has been stored is stored in a register IY.
Subsequently, checking conditions of switches, if any
25 switches are on, ROM addresses which have stored
software ^{routine} of functions corresponding to the switches are

stored in the register IX or IY. This operation is continued until a switch 71 of the OUT button 59 turns on.

When the switch 71 of the OUT button 59 turns
5 on, the interruption signal WINT is rendered "L" to set
a WRITE interruption to the main CPU 10. Subsequently,
an address into which a photometry routine is to be
transferred is stored in a register IW and an address
into which an AF routine is to be transferred is stored
10 in a register IZ. Then, contents of an address which is
indicated by the register IX are read in an accumulator
(Acc) to store them in an address indicated by the
register IW. This operation is continued to the final
address of the photometry routine. Then follows the
15 operation that contents of an address indicated by the
register IY ^{are} ~~is~~ stored in an address indicated by the
register IZ, in a manner similar to the above operation.
a
This operation is repeated to the final address of the
AF routine. When all transferring operations are
20 completed, the signal WINT is rendered "H" to check
again conditions of switches responding to the operating
buttons.

Fig. 15 is a modification of the second
embodiment of the present invention. The distinction
25 between the modification and the second embodiment is
that switch inputs are replaced by bar code inputs given

by a bar code reader. In Fig. 15, examples of bar codes are Photometry 1, Photometry 2, Photometry 3, AF single and AF continuous (84 to 88). It is possible to select a desired function by inputting it with a bar code reader 83 in a manner similar to the switch input.

As described with first and second embodiments, while a photographer selects desired functions and stores them in the camera body, it is possible to have functions other than those presented by a camera manufacturer by preparing and transferring softwares by a photographer himself.

Furthermore, while the ~~E2PROM~~^{E²PROM} is employed as a memory on the camera side, the same effects can be obtained even when a RAM having a backup function or a magnetic memory is employed.

In addition, all memories within the camera body may be rewritable with the ~~E2PROM~~^{E²PROM}.

In the first and second embodiments, if the second memory and data input portions within the camera body are rendered removable from the camera body, a photographer can select one of a plurality of prepared second memories to use it as occasion arises.
